Chapter 2: SYNTHESIS AND DISTRIBUTIONS

2.1 Distributions - Definitions

Distributions of molecular weights

- degree of polymerization \( N \) = number of monomers constituting the polymer
- molar mass \( m = N m_0 \) with \( m_0 \) = monomer molar mass
- mass of the polymer \( M = m / N_A \) with \( N_A \) = Avogadro number
- total mass \( M = \sum_i M_i \)
- total number \( n = \sum_i n_i \)

Polymerizations result in more or less broad distributions of molecular weights

- number fraction \( x_i = \frac{n_i(M_i)}{\sum_j n_j(M_j)} = \frac{n_i(M_i)}{n} \)
- weight fraction \( w_i = \frac{x_i M_i}{\sum_j x_j M_j} = x_i \frac{M_i}{M_n} \)
- \( z \)-fraction \( z_i = w_i(M_i) \frac{M_i}{M_w} \)

Distributions can be characterized by directly measurable moments \( \mu_k = \sum_i x_i M_i^k \)

- number average \( M_n = \frac{\sum_i x_i M_i}{\sum_i x_i} = \sum_i x_i M_i = \mu_1 / \mu_0 = \mu_1 \)
- weight average \( M_w = \frac{\sum_i x_i M_i^2}{\sum_i x_i M_i} = \frac{\sum_i x_i M_i^2}{M_n} = \sum_i w_i M_i = \mu_2 / \mu_1 \)
- \( z \)-average \( M_z = \frac{\sum_i x_i M_i^3}{\sum_i x_i M_i^2} = \frac{\sum_i w_i M_i^2}{M_w} = \frac{\sum_i w_i M_i^2}{M_w} = \mu_3 / \mu_2 \)
“Uneinheitlichkeit”

\[ u = \frac{\mu_2}{\mu_1^2} - 1 = \frac{M_w}{M_n} - 1 \]

“polydispersity”

\[ \frac{M_w}{M_n} \]

e.g. a distribution of 1000 spheres:

<table>
<thead>
<tr>
<th>number</th>
<th>number fraction</th>
<th>sphere mass</th>
<th>(x_iM_i)</th>
<th>(x_iM_i^2)</th>
<th>(x_iM_i^3)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>[g]</td>
<td>[g]</td>
<td>[10^2 g^2]</td>
<td>[10^4 g^3]</td>
</tr>
<tr>
<td>900</td>
<td>0.9</td>
<td>100</td>
<td>90</td>
<td>90</td>
<td>90</td>
</tr>
<tr>
<td>50</td>
<td>0.05</td>
<td>500</td>
<td>25</td>
<td>125</td>
<td>625</td>
</tr>
<tr>
<td>50</td>
<td>0.05</td>
<td>2500</td>
<td>125</td>
<td>3125</td>
<td>78125</td>
</tr>
</tbody>
</table>

moments \( \mu_1=240 \quad \mu_2=3340 \quad \mu_3=78840 \)

number average \( M_n = \mu_1 = 240 \text{ g} \)

weight average \( M_w = \frac{\mu_2}{\mu_1} = 1392 \text{ g} \)

z-average \( M_z = \frac{\mu_1}{\mu_2} = 2360 \text{ g} \)

"Uneinheitlichkeit" \( u = \frac{\mu_2}{\mu_1^2} - 1 = \frac{M_w}{M_n} - 1 = 4.8 \)

⇒ higher moments put stronger weight on heavier spheres.
Small number fractions of heavy spheres lead to drastic differences between the averages.

Averages

\[ M_\beta = \frac{\int_0^\infty x(M)M^\beta dM}{\int_0^\infty x(M)M^{\beta-1} dM} \]

with \( \beta=1,2,3 \) for n,w,z-average

\[ \int_0^\infty x(M)\ dM = 1 \]
averaging an arbitrary quantity \( A(M) \): 
\[
A_\beta = \int_{0}^{\infty} x(M) M^{\beta-1} A(M) \, dM \\
\int_{0}^{\infty} x(M) M^{\beta-1} \, dM
\]

Integral distributions \( X, W \) and \( Z \) yield the number average, mass average and \( z \)-average of a sample with \( M \leq M^* \), respectively: 
\[
X = \int_{0}^{M^*} x(M) \, dM, \quad W = \int_{0}^{M^*} w(M) \, dM \quad \text{and} \quad Z = \int_{0}^{M^*} z(M) \, dM.
\]

**e.g. Schulz-Zimm distribution \((k=2)\)** (see radical polymerization)

\( N_n : N_w : N_z = 1 : (3/2) : 2 \)

**Kinetics**

is the study of the speed at which chemical processes take place. In a chemical reaction it is the amount of product that forms or the amount of reactant that disappears in a given time interval and per unit volume.

**Molecular weight distributions**

can be calculated from 1. the kinetics of elementary chain reactions (e.g. radical and ionic polymerization) and 2. from probability calculations (e.g. polycondensation). In the following the distributions are derived for different polymerization methods:
2.2 Radical polymerization

monomer

\[
\begin{align*}
&\text{vinyl chloride} & \text{ethylene} & \text{propylene} & \text{styrene} \\
&\text{H} & \text{H} & \text{X} & \text{H} & \text{Cl} & \text{CH}_3 & \text{H}
\end{align*}
\]

initiator

Heating

polymerization

chain transfer

termination

combination

disproportionation
Kinetics: radical polymerization with combination termination

- **radical generation** \( I \rightarrow 2R^* \)
  \[
  V_{\text{start}} = -\frac{d[I]}{dt} = k_I[I] = 2\frac{d[R^*]}{dt}
  \]

- **termination** \( P_n^*+P_m^* \rightarrow P_{n+m} \)
  \[
  V_{\text{term}} = -\frac{d[P^*]}{dt} = k_2[P^*]^2
  \]

- **stability condition** \( V_{\text{start}} = V_{\text{term}} \)
  \[
  k_I[I] = k_2[P^*]^2
  \]

- **growth reaction** \( P_n^*+M \rightarrow P_{n+1} \)
  \[
  V_{\text{poly}} = -\frac{d[M]}{dt} = k_3[P^*][M] = k_4[I]^{1/2}[M]
  \]

\[ [M](t) = [M]_0 \exp(-k_4[I]^{1/2}t) \quad \text{conversion} \quad \frac{[M]_0 - [M]}{[M]_0} = 1 - \exp(-k_4[I]^{1/2}t) \]

**Derivation of the molecular weight distributions**

Termination by combination of chains but without participation of a free radical

(A) **generation of active monomers:**

\[
\frac{d[P^*_1]}{dt} = k_1[P^*_1][M] - k_p[P^*_1][P^*_1] - k_I[P^*_1][M^*] - k_t[P^*_1][P^*_2] - \ldots - k_{[P^*_1]}[P^*_x]
\]

(B) **generation of active dimers:**

\[
\frac{d[P^*_2]}{dt} = k_2[P^*_2][M] - k_p[P^*_2][P^*_1] - k_I[P^*_2][P^*_1] - k_t[P^*_2][P^*_2] - \ldots - k_{[P^*_2]}[P^*_x]
\]

(C) **generation of active x-mer:**

\[
\frac{d[P^*_x]}{dt} = k_x[P^*_{x-1}][M] - k_p[P^*_x][P^*_1] - k_I[P^*_x][P^*_1] - k_t[P^*_x][P^*_2] - \ldots - k_{[P^*_x]}[P^*_1]
\]

- **stationary state**
  \[
  \frac{d[P^*_1]}{dt} = \frac{d[P^*_2]}{dt} = \ldots = \frac{d[P^*_x]}{dt} = 0
  \]

- **rate of active monomer generation compensates all termination reactions**
  \[
  V_{\text{act}} = k[R][M] = k_I[P^*_1]
  \]
  where \([P^*]\) = sum of all active chains and monomers

- **[M] is (almost) constant for small conversions**
  \[
  0 = k[R][M] - k_p[P^*_1][M] - k_I[P^*_1][P^*]
  \]
  \[\Leftrightarrow\]
  \[
  V_{\text{act}} = k[R][M] = k_p[P^*_1][M] + k_I[P^*_1][P^*]
  \]

PD Dr. Silke Rathgeber
Johannes Gutenberg-University Mainz
Institute for Physics – KOMET 331
Staudingerweg 7
55099 Mainz
Germany

phone: +49 (0) 6131/ 392-3323
Fax: +49 (0) 6131/ 392-5441
email: s.rathgeber@uni-mainz.de
webpage: http://www.cond-mat.physik.uni-mainz.de/~rathgebts/
\[ \Rightarrow \frac{V_{ac}}{[M]k_p} = [P^*_1] \left( 1 + \frac{[P^*_r]k_r}{[M]k_p} \right) = [P^*_r](1 + \beta) \quad (*) \]

for all other equations analogous:\n\[
\Rightarrow [P^*_s] = \frac{[P^*_s]}{(1 + \beta)} = \ldots = \frac{[P^*_r]}{(1 + \beta)^s-1} = \frac{V_{ac}}{[M]k_p (1 + \beta)^s} \quad (**)
\]

dead chains are produced by two active chains:
\[
\Rightarrow \frac{d[P^*_1]}{dt} = k_i[P^*_1][P^*_1] \quad (*)
\]
\[
\Rightarrow [P^*_1] = k_i[P^*_1][P^*_1] \cdot t + \text{const} \quad \text{with} \quad \text{const} = [P^*_s]_{t=0} = 0 \quad (**)
\]
\[
\Rightarrow [P^*_1] = k_i \frac{V_{ac}}{[M]k_p (1 + \beta)^1} \cdot \frac{\beta k_r [M]}{k_t} \cdot t = \frac{V_{ac} \cdot \beta}{(1 + \beta)^1} \cdot t \quad (\times)
\]

• according to definition generates each activated monomer a polymer in the time \( t \) there are \( V_{ac} \cdot t = \sum [P^*_1] \) active monomers ⇔ polymers generated
\[
\Rightarrow x(N) = \frac{[P^*_1]}{\sum_x [P^*_1]} = \frac{\beta}{(1 + \beta)^N} \quad \text{number fraction distribution}
\]
\[
\Rightarrow N_n = \sum_N X(N) \cdot N = \frac{1 + \beta}{\beta} \quad \text{averages}
\]
\[
N_w = \sum_N X(N) \cdot N^2 = \frac{\beta + 2}{\beta}
\]
\[
N_z = \sum_N X(N) \cdot N^3 = \frac{\beta^2 + 6 \beta + 6}{(\beta + 2) \beta}
\]
\[
\Rightarrow w(N) = \frac{X(N) \cdot N}{N_n} = \frac{\beta^2 N}{(1 + \beta)^{N+1}} \quad \text{weight fraction distribution}
\]

for low radical concentrations (\( \beta \ll 1 \)):
\[
\Rightarrow N_n = \frac{1}{\beta} \quad ; \quad N_w = \frac{2}{\beta} \quad ; \quad N_z = \frac{3}{\beta}
\]
\[
\Rightarrow N_n \cdot N_w \cdot N_z = 1 : 2 : 3
\]
\[ N_w = 2 \quad \text{polydispersity} \]
\[ u = \frac{N_w}{N_a} - 1 = 1 \quad \text{“Uneinheitlichkeit”} \]

More general derivation leads to **Schulz-Zimm distribution**

- constant number of chains growth by random monomer addition until termination
- start of chain growth not necessarily at the same time
- concentration of active centers stays constant (stationarity condition)

\[
x(N) = \frac{\beta^k N^k \exp(-\beta N)}{\Gamma(k)} \quad \text{with} \quad \beta = \frac{k}{N_a} \\
\Rightarrow \quad w(N) = \frac{N}{N_a} x(N) = \frac{\beta^k N^k \exp(-\beta N)}{\Gamma(k) \cdot N_a} \quad \text{(typos in Elias)}
\]

\[ k = \text{degree of coupling} = \text{number of chain combined to dead chain in termination reaction} \]

\[ N_a = \frac{k}{\beta} \Rightarrow \frac{N_w}{N_a} = \frac{N_z}{k+1} = \frac{N_z}{k+2} \quad \text{(use integral definition)} \]

for \( k = 1 \)
\[ N_a = \frac{1}{\beta} \Rightarrow N_a : N_w : N_z = 1 : 2 : 3 \quad \text{(disproportionation)} \]

for \( k = 2 \)
\[ N_a = \frac{2}{\beta} \Rightarrow N_a : N_w : N_z = 1 : \frac{3}{2} : 2 \quad \text{(combination of two chains)} \]

\[ \Rightarrow \quad z(N) = \frac{w(N)}{N_w} = \frac{N}{N_a} \frac{k}{N_a} \quad \text{with} \quad N_w = \left( \frac{k+1}{k} \right) N_a \]

for radical polymerization with combination termination:
### 2.3 (An)ionic polymerization

**Initiator**

\[
\begin{align*}
H & - C - C - C - C - C'Li^+ = R'Li^+ \\
H & H & H & H & H
\end{align*}
\]

**Polymerization**

\[
\begin{align*}
R'Li^+ + C & = C \\
H & H & H & H & H \\
H & X
\end{align*} \rightarrow \begin{align*}
R - C - C'Li^+ \\
H & H & X & H & H
\end{align*} \rightarrow \begin{align*}
R - C - C - C - C'Li^+ \\
H & H & H & H & H
\end{align*}
\]

**Conversion**

\[
\begin{align*}
C & - Li^+ \\
H & X
\end{align*} + H - C - O - H \rightarrow \begin{align*}
C & - H \\
H & X
\end{align*} + H - C - O' Li^+
\]

**Kinetics: (An)ionic polymerization**

- no termination reaction
- concentration of active centers stays constant \([P^*]=\text{constant}\)
- all chains start to growth at the same time; instantaneously at \(t=0\)

**Growth reaction**

\[
P_n^* + M \rightarrow P_{n+1}
\]

\[
V_{poly} = -\frac{d[M]}{dt} = k_p [P^*][M]
\]

\[
[M](t) = [M]_0 \exp(-k_p [P^*]t)
\]

**Conversion**

\[
u = \frac{[M]_0 - [M]}{[M]_0} = 1 - \exp(-k_p [P^*]t)
\]

**Derivation of the molecular weight distributions**

- Initiator ions are instantaneously converted to monomer ions
- Number of initiator ions \([I] = [P_i^*]_{t=0}\) number of monomer ions

**Monomer**

\[
\frac{d[P_i^*]}{dt} = -k_p [M][P_i^*]
\]

**Dimer**

\[
\frac{d[P_2^*]}{dt} = -k_p [M][P_i^*] - k_p [M][P_2^*]
\]
x-mer
\[
\frac{d[P_x^*]}{dt} = -k_p [M][P_{x-1}^*] - k_p [M][P_x^*]
\]

reduction of monomer number is determined by the number of active centers
\[
\frac{d[M]}{dt} = -k_p [M][P_1^*]
\]
with \([P^*] = \sum_i [P_i^*] = [I] = [P_1^*]_{t=0} = \text{const}
\]
\(\text{number of growing chains}
\)

\[\nu = \frac{[M]_{t=0} - [M]}{[P^*]} - 1 = N_a - 1\]
\(\nu\) gives us the number of monomers attached to one monoion \(P^*\)
\[
\frac{d\nu}{dt} = -\frac{d[M]}{dt} \frac{1}{[P^*]} = k_p [M] \Leftrightarrow dt = \frac{1}{k_p [M]} d\nu
\]

\(\Leftrightarrow\) coupled differential equation system

monomer: \(d[P_1^*] = -k_p [P_1^*] d\nu\)

* dimer: \(d[P_2^*] = [P_1^*] d\nu - [P_2^*] d\nu\)

\[\vdots\]

\(x\)-mer: \(d[P_x^*] = [P_{x-1}^*] d\nu - [P_x^*] d\nu\)

(1) solution monomer: \(P_1^* = C \exp(-\nu)\) with \([P_1^*]_{t=0} = [P^*] = [P_1^*]_{t=0}\)
\[\Rightarrow [P_1^*] = [P^*] \exp(-\nu)
\]

(2) solution dimer: \(d[P_2^*] = [P^*] \exp(-\nu) d\nu - [P_2^*] d\nu\)

solved by general solution of homogenous differential equation + special solution of inhomogeneous differential equation

hom. solution: \([P_2^*]_h = C_1 \exp(-\nu)\)

inhom. solution: ansatz variation of constant \([P_2^*]_h = C(\nu) \exp(-\nu)\)

\[\Rightarrow \frac{d[P_2^*]}{d\nu} = \frac{dC(\nu)}{d\nu} \exp(-\nu) - C(\nu) \exp(-\nu) = [P^*] \exp(-\nu) - C(\nu) \exp(-\nu)
\]
\[\Rightarrow \frac{dC(\nu)}{d\nu} = [P^*] \Rightarrow C(\nu) = [P^*] \nu + C_2
\]

\[\Rightarrow \text{general solution} \ [P_2^*] = [P_2^*]_h + [P_2^*]_s = ([P^*] \nu + C) \exp(-\nu) \text{ with}
\]
\([P^*]_{t=0} = 0 = [P_2^*]_{t=0}\)
\[\Rightarrow [P_2^*] = [P^*] \cdot \nu \cdot \exp(-\nu)\]
(3) solution trimer: \[
[P_3^*] = \frac{\nu^2 [P^*]\exp(-\nu)}{2!}
\]
by induction method => for the \((x-1)\)mer: \[
[P_{x-1}^*] = \frac{\nu^{x-2} [P^*]\exp(-\nu)}{(x-2)!}
\]
to solve the \(x\)th differential equation:
\[
\frac{d[P_x^*]}{dx} = \frac{\nu^{x-2} [P^*]\exp(-\nu)}{(x-2)!} d\nu - [P_x^*]
\]
general hom. solution: \[
[P_x^*]_o = C_1 \exp(-\nu)
\]
special inhom. solution: \[
[P_x^*] = C(\nu) \exp(-\nu)
\]
\[
\Rightarrow \frac{dC(\nu)}{d\nu} = \frac{\nu^{x-2} [P^*]}{(x-2)!} \Rightarrow C(\nu) = \frac{\nu^{x-1} [P^*]}{(x-1)!} + C_2 \text{ with } [P_x^*]_{\nu=0} = 0 = [P_x^*]_{\nu=0}
\]
\[
\Rightarrow [P_x^*] = \frac{\nu^{x-1} [P^*]}{(x-1)!} \exp(-\nu) \quad \text{general solution}
\]
⇒ number fraction of polymers with degree of polymerization \(N\):
\[
\Rightarrow x(N) = \frac{[P_x^*]}{[P_x^*]} = \frac{\nu^{N-1} \exp(-\nu)}{(N-1)!} \quad \text{with } \nu = N_n - 1 \quad \text{Poisson distribution}
\]
\[
\Rightarrow N_n = \sum_{N=1}^{\infty} x(N) N = \nu + 1 = N_n \quad \text{averages}
\]
\[
N_w = \sum_{N=1}^{\infty} x(N) N^2 = \frac{\nu^2 + 3\nu + 1}{1 + \nu} = \frac{N_n^2 + N_n - 1}{N_n} = N_n + 1 - \frac{1}{N_n}
\]
\[
N_z = \sum_{N=1}^{\infty} x(N) N^3 = \frac{1 + 7\nu + 6\nu^2 + \nu^3}{1 + 3\nu + \nu^2} = \frac{N_n^3 + 3N_n^2 - 2N_n - 1}{N_n^2 + N_n - 1}
\]

polydispersity:
\[
\frac{N_w}{N_z} = \frac{N_n + 1}{N_n^2} = 1 + \frac{(N_n - 1)}{N_n^2} \approx 1 + \frac{1}{N_n}
\]

“Uneinheitlichkeit”
\[
u = \frac{N_n - 1}{N_n^2} \approx \frac{1}{N_n}
\]

weight fraction distribution
\[
w(N) = x(N) \frac{N}{N_n} = x(N) \frac{N}{\nu + 1} = \frac{N \cdot \nu^{N-1} \exp(-\nu)}{(N-1)! (\nu + 1)}
\]
Comparison distributions ionic and radical polymerization

Schulz-Zimm (k=2)  \[ N_n: N_w: N_z = 1: (3/2): 2 \]

Poisson  \[ N_w: N_n = 1 + N_n^{-1} \]

Schulz-Zimm distribution

[Graph showing Schulz-Zimm and Poisson distributions]

Schulz-Zimm (k=2) and Poisson distribution

[Graph comparing Schulz-Zimm and Poisson distributions]

same mean degree of polymerization \( N_n = 50 \)
2.3 Polycondensation

e.g. polyester

A = di-acid = adipic acid, terephthalic acid

\[ -(CH_2)_4-; -\bigcirc - \]

B = di-alcohol = ethylene glycol; butanediol

\[ -(CH_2)_2-; -(CH_2)_4- \]

- chain growth reaction: \((AB)_x + A \ B + (AB)_x \ (AB)_x + (AB)_y\)
- stoichiometric ratio of acid/alcohol has strong impact on the final molecular weight
- termination: chain closure, monofunctional impurities

Kinetics: polycondensation

A = di-acid; B = di-alcohol

- no termination reaction
- acid acts as catalyst \([A]=[C]\)
- \([A]=[B]\)

\[ V_{poly} = \frac{d[A]}{dt} = k[C][A][B] = k[A]^3 \]

\[ \Leftrightarrow \frac{[A](t)}{[A]^3} = 2kt + \frac{1}{[A]_0^3} \]

\[ \Leftrightarrow \frac{[A]_0^3}{[A](t)} - 1 = [A]^3, 2kt \]

\[ \Leftrightarrow [A](t) = \frac{1}{\sqrt{2kt + [A]_0^{-2}}} \]

conversion

\[ u = 1 - \frac{1}{\sqrt{2kt[A]_0^2 + 1}} \]
• no side reactions, i.e. no termination
• A and B are bifunctional

define \( r_0 = \left( \frac{n_A^0}{n_B^0} \right) \leq 1 \) (stoichiometric ratio)

\[ n_M = \frac{n_A^0 + n_B^0}{2} = \frac{n_A^0}{2} [1 + r_0] \]

number of functional groups after time t:

\[ n_A = n_A^0 - p_A n_A^0 \quad \text{and} \quad n_B = n_B^0 - p_B n_B^0 = n_B^0 - p_A n_A^0 \]

\[ n_E = n_A + n_B = n_A^0 (1 - 2 p_A) + n_B^0 = n_A^0 (1 - 2 p_A) + n_A^0 \cdot r_0^{-1} = n_A^0 (1 - 2 p_A + r_0^{-1}) \]

\[ N_n = 2 \frac{n_N}{n_E} \quad \text{(bifunctional groups)} \]

\[ N_n = \frac{(1 + r_0^{-1})}{(1 - 2 p_A + r_0^{-1})} = \frac{r_0 + 1}{1 + r_0 - 2 p_A \cdot r_0} \]

limits

• for \( r_0 = 1 \) and \( p_A = 1 \) \( \Rightarrow N_n = \infty \) (one long chain)
• for \( r_0 < 1 \) and \( p_A = 1 \) \( \Rightarrow N_n = \frac{1 + r_0}{1 - r_0} \quad r_0 = 0.99 \quad \Rightarrow \quad N_n = 199 \)
• for \( r_0 = 1 \) and \( p_A > 1 \) \( \Rightarrow N_n = \frac{1}{1 - p_A} \quad p_A = 0.99 \quad \Rightarrow \quad N_n = 100 \)
• for \( r_0 = 1 \) \( \text{ABABAB} \) A and B ends with same probability
  \( r_0 < 1 \) \( \text{BABAB} \) same ends with excess component
N_n as a function of conversion

\[ N_n \text{ as a function of the stoichiometric ratio } r_0 = n_A^0 / n_B^0 \]
Derivation of molecular weight distributions

Derivation not from kinetics but by probability treatment

- \( r_0 = 1 \)
- all functional groups have the same reaction probability

\( p \) = conversion of reaction
\( p-1 \) = fraction of non reacted groups

\begin{itemize}
  
  \item \( n = 0 \)
  
  \item \( n \) dimer is build with the probability \( p \)
  
  \item \( n \) trimer \( p^2 \)
  
  \item \( n \) tetramer \( p^3 \)
  
  \item : \( n \) x-mer \( p^{n-1} \)

\end{itemize}

\( \Rightarrow \) the probability to find a polymer with \( N \) monomers \( p_N = \frac{(p^{N-1})}{(1-p)} \)

\( x(N) = \frac{N_{\text{total}} \times P_N}{N_{\text{total}}} = p^{N-1}(1-p) \) \( \Rightarrow \) number fraction distribution

\( w(N) = x(N) \cdot \frac{N}{N_n} = p^{N-1}(1-p) \cdot \frac{N}{N_n} \) \( \Rightarrow \) weight fraction distribution

\( \Rightarrow \) \( N_n = \sum_{N=1}^{\infty} x(N)N = \frac{1}{1-p} \) \( \Rightarrow \) averages

\( N_w = \sum_{N=1}^{\infty} x(N)N^2 = \frac{1+p}{1-p} \)

\( N_z = \sum_{N=1}^{\infty} x(N)N^3 = \frac{p^2+4p+1}{1-p^2} \)

polydispersity

\( \frac{N_w}{N_n} = p+1 \)

“Uneinheitlichkeit”

\( u = \frac{N_n}{N_w} - 1 = p \)

weight fraction distribution

\( w(N) = p^{N-1}(1-p) \cdot \frac{N}{N_n} = p^{N-1}(1-p)^2N \)
weight fraction distribution

number fraction distribution
2.4 Metalocene catalysts

Positively charged metal ion sandwiched between to negatively charged cyclopentadienyl anions

empty site at the Zr complex is occupied by dative bonded ethylene.

complexation with a monomer

destabilization of double bond

insertion of ethylene
complexation with a monomer

\[
\begin{align*}
\text{Zr} & \\

(L-Reaction) Polycondensation

(O-Reaction) Polyaddition

production of reaction products $L$

Choice of synthesis method and varying control of termination reactions has significant impact on the distributions of the resulting molecular weights!
2.4 Determination of Molecular Weight Distributions

1. Gel permeation chromatography (GPC)  
   distribution; $M_w$, $M_n$  
2. Ultracentrifugation  
   $M_z$ & $M_w$  
3. Matrix assisted Laser Desorption/Ionisation- Time-of-Flight (MALDI - TOF)  
   distribution; $M_w$, $M_n$  
4. Scattering methods (see Chap. 5)  
5. Membrane osmometry (see Chap. 4)  
6. Viscosimetry  
   between $M_w$ & $M_n$

2.4.1 Gel Permeation Chromatography (GPC)

also: SEC (Size or Steric Exclusion Chromatography)

Separation principle

\[
V_e = V_0 + K_{SEC}V_i \\
0 \leq K_{SEC} \leq 1
\]

with

$V_e$ = elution volume  
$V_i$ = total pore volume  
$V_0$ = volume outside pores

$K_{SEC} = 0$ for molecules bigger than largest pore size  
$K_{SEC} = 1$ for small molecules for which the total pore volume $V_i$ is accessible.

GPC measures the hydrodynamic volume of a polymer

\[
V_e \propto R_H
\]

Separation is due to changes in the Gibb's free enthalpy when crossing over from the mobile to the stationary phase:

\[
\Delta G = \Delta H - T\Delta S = -k_B N_A T \ln K_{SEC}
\]

with $\Delta H$= enthalpy change and $\Delta S$= entropy change
Ideally, separation is not due to interactions between polymer and column material, but is due to molecular weight dependent changes in entropy when crossing over from the mobile to the stationary phase.

Ideal separation results from changes in entropy only $\Delta H = 0$

$$K_{SEC} = \exp\left(-\frac{\Delta S}{k_B N_A}\right)$$

**Experimental setup**

- **mobile phase:** good solvent for polymers
- **column:** porous material, such as silica or swollen polymeric gels made of styrene & divinylbenzene
- **detectors:** refractive index, absorption UV-VIS, viscosity

**transformations:**
1. signal to concentration
2. time to elution volume
3. elution volume to molar mass

Calibration with defined standards

In a limited region there is a linear relation between $\log(M)$ and $V_e$: $$\log M = A + BV_e$$
Universal calibration

Elution volume $V_E$ is proportional to the hydrodynamic radius $R_H$
$R_H$ is proportional to the product of molecular weight $M$ and intrinsic viscosity $\eta$

$$V_E \propto R_H \propto M \eta$$

Diagram, where the product $M \eta$ is plotted versus $V_e$ should lead to master curve for different polymers

$$(M_1 \eta_1)_{V_e} = (M_2 \eta_2)_{V_e}$$

$\eta$ is a function of molecular weight (Mark-Houwink relation): $\eta = c M^\alpha$

$$\Rightarrow \quad (c_1 M_1^{\alpha+1})_{V_e} = (c_2 M_2^{\alpha+1})_{V_e}$$

Calibration of the column with polymer 1 $\Rightarrow$ molecular weight of second polymer if $c_i$ and $\alpha_i$ are known (Literature: "Polymerhandbook")

$$\ln M_2 = \frac{1}{1+\alpha_2} \ln \frac{c_1}{c_2} + \frac{1+\alpha_2}{1+\alpha_1} \ln M_1$$

universal calibration $M_2 = M_1 \frac{\eta_1}{\eta_2}$
2.5.2 Ultracentrifugation

\[ f = \text{friction coefficient} \]
\[ \omega = \text{angular velocity} \]
\[ D = \text{diffusion coefficient} \]
\[ \rho_s = \text{solvent density} \]
\[ \upsilon_p = \text{partial specific volume polymer} \]

\[ \text{friction} \quad f \frac{dx}{dt} \]
\[ \text{centrifugal force} \quad m_{\text{eff}} \omega^2 x \]
\[ \text{buoyancy} \quad \frac{M}{N_A} \rho_s \upsilon_p \omega^2 x \]

Measuring principle

Superposition of sedimentation and diffusion

1. Sedimentation velocity method

- fast rotation \( \approx 60000 \text{rpm} \)
- centrifugal acceleration stronger than diffusion
- temporal development of concentration profile is detected.
- "fast" (2h); diffusion coefficient needs to be known; complicated averages.

\( \rho_{\text{solvent}} > \rho_{\text{polymer}} \Rightarrow \text{flotation} \)
\( \rho_{\text{solvent}} < \rho_{\text{polymer}} \Rightarrow \text{sedimentation} \)
Ansatz balance of forces: centrifugal force = frictional force  \[ m_{\text{eff}} \omega^2 x = f \frac{dx}{dt} \]
effective mass due to buoyant force  \[ m_{\text{eff}} = \frac{M}{N_A} \left( 1 - \rho_s \nu_p \right) \]

with  \[ f = \frac{k_B T}{D} \]

\[ D \text{ determined by independent experiment dynamic light scattering} \]

\[ M = \frac{dx}{dt} \frac{N_A k_B T}{\omega^2 D} \left( 1 - \rho_s \nu_p \right)^{-1} \]
detection of profile with time

PD Dr. Silke Rathgeber  
Johannes Gutenberg-University Mainz  
Institute for Physics – KOMET 331  
Staudingerweg 7  
55099 Mainz  
Germany

phone: +49 (0) 6131/ 392-3323  
Fax: +49 (0) 6131/ 392-5441  
email: s.rathgeber@uni-mainz.de  
webpage: http://www.cond-mat.physik.uni-mainz.de/~rathgebs/
2. Sedimentation equilibrium method

- slower rotation < 20000 rpm
- equilibrium between sedimentation and diffusion; radial concentration profile is detected.
- "time consuming" (24h); all averages can be determined.

In addition: diffusion mass current = sedimentation mass current

1. Fick’s law

\[ \frac{dm_D}{dt} = -Dq \frac{\partial c}{\partial x} = \frac{dm_s}{dt} = cd \frac{\partial c}{\partial t} \Rightarrow c \frac{\partial c}{\partial t} = -D \frac{\partial c}{\partial x} \]

with \( M = \frac{dx}{dt} \frac{k_B N_A T}{\rho \omega^2 D} \left(1 - \rho_s \rho_p \right)^{-1} \)

\[ \frac{1}{c} \frac{\partial c}{\partial x} = \frac{M \omega^2 x \left(1 - \rho_s \rho_p \right)}{k_B N_A T} \]

\[ \Rightarrow c = c(x_b) \exp \left[ \frac{M}{2 k_B N_A T} \left(1 - \rho_s \rho_p \right) \omega^2 (x^2 - x_b^2) \right] \]  

monodisperse sample

for a polydisperse sample:

\[ \frac{\partial c}{\partial x} = \frac{\omega^2 x \left(1 - \rho_s \rho_p \right)}{k_B N_A T} \sum_i c_i M_i \]

take average at each sample position \( x \)

\[ M_w(x) = \frac{\sum_i c_i(x) M_i}{\sum_i c_i(x)} = \frac{\partial c}{\partial x} \frac{1}{c(x)} \frac{k_B N_A T}{\omega^2 x \left(1 - \rho_s \rho_p \right)} \]

then integrate over whole sample

\[ M_w = \frac{\int_{x_m}^{x_b} M_w(x) xc_i(x) dx}{\int_{x_m}^{x_b} xc_i(x) dx} = \frac{k_B N_A T \left[c(x_b) - c(x_m)\right]}{\omega^2 \left(1 - \rho_s \rho_p \right) \int_{x_m}^{x_b} xc_i(x) dx} \]

\( M_n \) and \( M_z \) analogous (see Arndt/Müller)

Ulcentrifugation is time-consuming (data collection & evaluation) and involves substantial experimental efforts.

**When useful?**

1. very large molecular masses; broad working range from \( 10^3 \) to \( 10^7 \) g/mole.
2. polymers interacting with column material.
3. distinction between polymer mixtures and diblock-copolymers determination of chemical heterogeneity of block-copolymers density gradient.
4. size determination of polymeremulsions in water or organic solvents.
2.5.3 MALDI-TOF
Matrix Assisted Laser Desorption Ionization-Time-of-Flight Mass Spectrometry

Measuring principle

\[ zV_0 = \frac{M}{2} v^2 = \frac{M}{2} \left( \frac{s}{t} \right)^2 \Rightarrow M = 2zV_0 \left( \frac{t}{s} \right)^2 \]

\( t = \) flight time;
\( s = \) flight path length (typically 1m)
\( z = \) charge
\( V_0 = \) potential difference (typically 20 kV)
\( M = \) mass
\( v = \) velocity

A mass difference of 1 amu correspond to a flight time of about 10 ns

1 amu = 1.66053886 \times 10^{-27} \text{ kg} \iff 1 \text{ g/mole}

One monomer unit with a mass of approximately 100 g/mole has a flight time of 1 \mu s.
Matrix

1. must be activateable at laser wave length (about 330nm).
2. must transfer a proton to the polymer (proton donator).
3. must solve the polymer.
4. must not react with polymer.
5. is typically a crystalline solid material.
